The denatured state dictates the topology of two proteins with almost identical sequence but different native structure and function.
The denatured state dictates the topology of two proteins with almost identical sequence but different native structure and function.

**Abstract**
The protein folding problem is often studied by comparing the mechanisms of proteins sharing the same structure but different native folding pathways. This work shows that the denatured state is committed very early along the folding pathway, being imprinted in the residual structure of the denatured state.
