Proflavine acts as a Rev inhibitor by targeting the high-affinity Rev binding site of the Rev responsive element of HIV-1.
Proflavine acts as a Rev inhibitor by targeting the high-affinity Rev binding site of the Rev responsive element of HIV-1.

Rev is an essential regulatory HIV-1 protein that binds the Rev responsive element (RRE) within the env gene of the HIV-1 to regulate gene expression. The high-affinity Rev binding site is a critical target for developing inhibitors that could theoretically bind to and compete with Rev for interactions with the RRE. This binding site opens the possibility for rational drug design based on linking and modifying it and related compounds.
